## 2 Fundamental Algebra

### 2.1 Matrix Classes

#### 2.1.1 Rotation Matrix

$$R = \begin{bmatrix} \cos \theta & \sin \theta \\ \sin \theta & \cos \theta \end{bmatrix}$$

- Orthogonal: Matrix times its transpose equals the identity  $RR^T = I$
- Special orthogonal: Determinant is  $+1$
- Closed under multiplication: The product of any two rotation matrices is another rotation matrix
- The inverse of a rotation matrix is also a rotation matrix

#### 2.1.2 Matrix Derivatives

$A(t)$

$$\dot{A}(t) = \begin{bmatrix} \frac{dR_{11}(t)}{dt} & \frac{dR_{12}(t)}{dt} \\ \frac{dR_{21}(t)}{dt} & \frac{dR_{22}(t)}{dt} \end{bmatrix}$$

$$\frac{d}{dt}(A \pm B) = \dot{A} \pm \dot{B}$$

$$\frac{d}{dt}(AB) = \dot{A}B + A\dot{B}$$

$$\frac{d}{dt}(A(\theta(t))) = \frac{dA}{d\theta}\dot{\theta}$$

#### 2.1.3 Jacobian

#### 2.1.4 Hessian

#### 2.1.5 Eigendecomposition

### 3 Fundamental Analysis

## 4 Fundamental Probability

## 5 Fundamental Mechanics

### 5.1 Coordinate Frames

#### 5.1.1 Inertia Frame of Reference

An inertial frame is a frame with constant acceleration i.e.  $\mathbf{a} = 0$ . A body with zero net force acting upon it is not accelerating within the inertial frame; that is, such a body is at rest or it is moving at a constant speed in a straight line.

### 5.2 Sources

### 5.3 Definitions

Transformation from coordinate frame B to frame A

$${}^A\mathbf{A}_B, {}^A\mathbf{R}_B$$

#### 5.3.1 Rigid Body Transformation

- length is preserved  $\|g(p) - g(q)\| = \|p - q\|$
- cross product is preserved  $g_*(v) \times g_*(w) = g_*(v \times w)$
- inner product is preserved  $g_*(v) \cdot g_*(w) = v \cdot w$

### 5.4 Rotation Group $SO(3)$

$$SO(3) = \{\mathbf{R} \in \mathbb{R}^3 | \mathbf{R}^T \mathbf{R} = \mathbf{R} \mathbf{R}^T = \mathbf{I}, \det \mathbf{R} = 1\}$$

#### 5.4.1 Rotation Matrices

#### 5.4.2 Euler Angles

#### 5.4.3 Axis Angle Parametrization

Rodrigues' formula

#### 5.4.4 Quaternions

### 5.5 Time Derivatives of Rotations

$$R^T(t) \dot{R}(t) = I \frac{d}{dt}(\cdot) \dot{R}^T R + R^T \dot{R} = 0$$

$$R(t) \dot{R}^T(t) = I \frac{d}{dt}(\cdot) R \dot{R}^T + \dot{R} R^T = 0$$

$R^T \dot{R}$  and  $\dot{R} R^T$  are skew symmetric

## 5.6 Skew Symmetric

### 5.6.1 Transformation vs Displacement

## 5.7 Momentum

### 5.7.1 Linear Momentum

### 5.7.2 Angular Momentum

$${}^A\mathbf{H}_C^B = \mathbf{I}_C \cdot {}^A\omega^B$$

Angular momentum  $\mathbf{H}$  with inertia tensor  $\mathbf{I}$  with  $C$  as the origin and angular velocity  $\omega$  of the body  $B$  in coordinate frame  $A$ .

### 5.7.3 Rate of Change of Angular Momentum

The rate of change of angular momentum of the rigid body  $B$  relative to  $C$  in  $A$  is equal to the resultant moment of all external forces  $\mathbf{M}$  acting on the body  $B$  relative to  $C$ .

$$\frac{{}^A d {}^A\mathbf{H}_C^B}{dt} = \mathbf{M}_C^B$$

Simplification

$$\frac{{}^B d {}^A\mathbf{H}_C^B}{dt} + {}^A\omega^B \times \mathbf{H}_C = \mathbf{M}_C^B$$

$$\begin{bmatrix} I_{11} & 0 & 0 \\ 0 & I_{22} & 0 \\ 0 & 0 & I_{33} \end{bmatrix} \begin{bmatrix} \dot{\omega}_1 \\ \dot{\omega}_2 \\ \dot{\omega}_3 \end{bmatrix} + \begin{bmatrix} 0 & -\omega_3 & \omega_2 \\ \omega_3 & 0 & -\omega_1 \\ -\omega_2 & \omega_1 & 0 \end{bmatrix} \begin{bmatrix} I_{11} & 0 & 0 \\ 0 & I_{22} & 0 \\ 0 & 0 & I_{33} \end{bmatrix} \begin{bmatrix} \omega_1 \\ \omega_2 \\ \omega_3 \end{bmatrix} = \begin{bmatrix} M_{C,1} \\ M_{C,2} \\ M_{C,3} \end{bmatrix}$$

The second term on the left hand side,  ${}^A\omega^B \times \mathbf{H}_C$ , is zero when angular velocity  ${}^A\omega^B$  is perpendicular to  $\mathbf{H}_C$ . This is the case if the body rotates around a **principal axis of inertia**.

## 5.8 Moment of Inertia

The moment of inertia  $\mathbf{I}$  is a tensor that determines the torque needed for a desired angular acceleration about a rotational axis; similar to how mass determines the force needed for a desired acceleration. It depends on the body's mass distribution and the axis chosen, with larger moments requiring more torque to change the body's rotation. It is an **additive** property: for a point mass the moment of inertia is just the mass  $m$  times the square of the distance  $r$  to the rotation axis.

$$\mathbf{I} = mr^2$$

For bodies free to rotate in 3D, their moments can be described by a symmetric 3x3 matrix, with a set of mutually perpendicular **principal axes** for which this matrix is diagonal and torques around the axes act **independently** of each other.

### 5.8.1 Principal Axis of Inertia

Measured in the body frame the inertia matrix is a constant real symmetric matrix. A real symmetric matrix has the eigendecomposition into the product of a rotation matrix  $\mathbf{Q}$  and a diagonal matrix  $\mathbf{\Lambda}$ .

$$\mathbf{I}_C^B = \mathbf{Q}\mathbf{\Lambda}\mathbf{Q}^\top$$

where

$$\mathbf{\Lambda} = \begin{bmatrix} I_1 & 0 & 0 \\ 0 & I_2 & 0 \\ 0 & 0 & I_3 \end{bmatrix}$$

The columns of the rotation matrix  $\mathbf{Q}$  define the directions of the principal axes of the body, and the constant  $I_1, I_2$  and  $I_3$  are called the **principal moments of inertia**.
